

nag_corr_cov (g02bxc)

1. Purpose

nag_corr_cov (g02bxc) calculates the Pearson product-moment correlation coefficients and the variance-covariance matrix for a set of data. Weights may be used.

2. Specification

```
#include <nag.h>
#include <nagg02.h>

void nag_corr_cov(Integer n, Integer m, double x[], Integer tdx,
                  Integer sx[], double wt[], double *sw, double wmean[], double std[],
                  double r[], Integer tdr, double v[], Integer tdv, NagError *fail)
```

3. Description

For n observations on m variables a one-pass updating algorithm (see West 1979) is used to compute the means, the standard deviations, the variance-covariance matrix, and the Pearson product-moment correlation matrix for p selected variables. Suitable weights may be used to indicate multiple observations and to remove missing values.

The quantities are defined by:

(a) The means

$$\bar{x}_j = \frac{\sum_{i=1}^n w_i x_{ij}}{\sum_{i=1}^n w_i} \quad j = 1, \dots, p$$

(b) The variance-covariance matrix

$$C_{jk} = \frac{\sum_{i=1}^n w_i (x_{ij} - \bar{x}_j)(x_{ik} - \bar{x}_k)}{\sum_{i=1}^n w_i - 1} \quad j, k = 1, \dots, p$$

(c) The standard deviations

$$s_j = \sqrt{C_{jj}} \quad j = 1, \dots, p$$

(d) The Pearson product-moment correlation coefficients

$$R_{jk} = \frac{C_{jk}}{\sqrt{C_{jj} C_{kk}}} \quad j, k = 1, \dots, p$$

where x_{ij} is the value of the i th observation on the j th variable and w_i is the weight for the i th observation which will be 1 in the unweighted case.

Note that the denominator for the variance-covariance is $\sum_{i=1}^n w_i - 1$, so the weights should be scaled so that the sum of weights reflects the true sample size.

4. Parameters

n

Input: the number of observations in the data set, n .

Constraint: $\mathbf{n} > 1$.

m

Input: the total number of variables, m .

Constraint: $\mathbf{m} \geq 1$.

x[n][tdx]

Input: the data $\mathbf{x}[i-1][j-1]$ must contain the i th observation on the j th variable, x_{ij} , for $i = 1, \dots, n; j = 1, \dots, m$.

tdx

Input: the second dimension of the array \mathbf{x} as declared in the function from which nag_corr_cov is called.

Constraint: $\mathbf{tdx} \geq \mathbf{m}$.

sx[m]

Input: indicates which p variables to include in the analysis.

If $\mathbf{sx}[j-1] > 0$, the j th variable is to be included.

If $\mathbf{sx}[j-1] = 0$, the j th variable is not to be included.

If \mathbf{sx} is set to the null pointer (Integer *)0 then all variables are included in the analysis, i.e., $p = m$.

Constraint: $\mathbf{sx}[i] \geq 0$, for $i = 1, \dots, m$.

wt[n]

Input: the optional frequency weighting for each observation. $\mathbf{wt}[i-1]$ contains the weight for the i th data value. Usually $\mathbf{wt}[i-1]$ will be an integral value corresponding to the number of observations associated with the i th data value, or zero if the i th data value is to be ignored.

If \mathbf{wt} is set to the null pointer (double *)0 then \mathbf{wt} is not referenced.

Constraint: $\mathbf{wt}[i-1] \geq 0.0$, for $i = 1, \dots, n$.

sw

Output: the sum of weights if \mathbf{wt} is not the null pointer, otherwise \mathbf{sw} contains the number of observations, n .

wmean[m]

Output: the sample means. $\mathbf{wmean}[j-1]$ contains the mean for the j th variable.

std[m]

Output: the standard deviations. $\mathbf{std}[j-1]$ contains the standard deviation for the j th variable.

r[m][tdr]

Output: the matrix of Pearson product-moment correlation coefficients. $\mathbf{r}[j-1][k-1]$ contains the correlation between variables j and k , for $j, k = 1, \dots, p$.

tdr

Input: the second dimension of the array \mathbf{r} as declared in the function from which nag_corr_cov is called.

Constraint: $\mathbf{tdr} \geq \mathbf{m}$.

v[m][tdv]

Output: the variance-covariance matrix. $\mathbf{v}[j-1][k-1]$ contains the covariance between variables j and k , for $j, k = 1, \dots, p$.

tdv

Input: the second dimension of the array \mathbf{v} as declared in the function from which nag_corr_cov is called.

Constraint: $\mathbf{tdv} \geq \mathbf{m}$.

fail

The NAG error parameter, see the Essential Introduction to the NAG C Library.

5. Error Indications and Warnings

NE_INT_ARG_LT

On entry, \mathbf{n} must be greater than 1: $\mathbf{n} = \langle \text{value} \rangle$.

NE_INT_ARG_LT

On entry, \mathbf{m} must not be less than 1: $\mathbf{m} = \langle \text{value} \rangle$.

NE_2_INT_ARG_LT

On entry, **tdx** = ⟨value⟩ while **m** = ⟨value⟩.
 These parameters must satisfy **tdx** \geq **m**.
 On entry, **tdr** = ⟨value⟩ while **m** = ⟨value⟩.
 The parameters must satisfy **tdr** \geq **m**.
 On entry, **tdv** = ⟨value⟩ while **m** = ⟨value⟩.
 These parameters must satisfy **tdv** \geq **m**.

NE_NEG_WEIGHT

On entry, at least one of the weights is negative.

NE_NEG_SX

On entry, at least one element of **sx** is negative.

NE_POS_SX

On entry, no element of **sx** is positive.

NE_SW_LT_ONE

On entry, the sum of weights is less than 1.0.

NE_VAR_EQ_ZERO

A variable has zero variance.
 At least one variable has zero variance. In this case **v** and **std** are as calculated, but **r** will contain zero for any correlation involving a variable with zero variance.

NE_ALLOC_FAIL

Memory allocation failed.

6. Further Comments

Correlation coefficients based on ranks can be computed using nag_ken_spe_corr_coeff (g02brc).

6.1. Accuracy

For a discussion of the accuracy of the one pass algorithm see Chan *et al* (1982) and West (1979).
