

nag_regsn_mult_linear_delete_var (g02dfc)

1. Purpose

nag_regsn_mult_linear_delete_var (g02dfc) deletes an independent variable from a general linear regression model.

2. Specification

```
#include <nag.h>
#include <nagg02.h>

void nag_regsn_mult_linear_delete_var(Integer ip, double q[],
    Integer tdq, Integer indx, double *rss, NagError *fail)
```

3. Description

When selecting a linear regression model it is sometimes useful to drop independent variables from the model and to examine the resulting sub-model. **nag_regsn_mult_linear_delete_var** updates the QR decomposition used in the computation of the linear regression model. The QR decomposition may come from **nag_regsn_mult_linear (g02dac)**, **nag_regsn_mult_linear_addrem_obs (g02dcc)**, **nag_regsn_mult_linear_add_var (g02dec)** or a previous call to **nag_regsn_mult_linear_delete_var**.

For the general linear regression model with p independent variables fitted, **nag_regsn_mult_linear (g02dac)** or **nag_regsn_mult_linear_add_var (g02dec)** computes a QR decomposition of the (weighted) independent variables and forms an upper triangular matrix R and a vector c . To remove an independent variable R and c have to be updated. The column of R corresponding to the variable to be dropped is removed and the matrix is then restored to upper triangular form by applying a series of Givens rotations. The rotations are then applied to c . Note that only the first p elements of c are affected.

The method used means that while the updated values of R and c are computed an updated value of Q from the QR decomposition is not available so a call to **nag_regsn_mult_linear_add_var (g02dec)** cannot be made after a call to **nag_regsn_mult_linear_delete_var**.

nag_regsn_mult_linear_upd_model (g02ddc) can be used to calculate the parameter estimates, $\hat{\beta}$, from the information provided by **nag_regsn_mult_linear_delete_var**.

4. Parameters

ip

Input: the number of independent variables already in the model, p .
Constraint: **ip** ≥ 1 .

q[ip][tdq]

Input: the results of the QR decomposition as returned by **nag_regsn_mult_linear (g02dac)**, **nag_regsn_mult_linear_addrem_obs (g02dcc)**, **nag_regsn_mult_linear_add_var (g02dec)** or previous calls to **nag_regsn_mult_linear_delete_var**.

Output: the updated QR decomposition. The first **ip** elements of the first column of **q** contain the updated value of c , the upper triangular part of columns 2 to **ip** contain the updated R matrix.

tdq

Input: the last dimension of the array **q** as declared in the function from which **nag_regsn_mult_linear_delete_var** is called.

Constraint: **tdq** \geq **ip**+1.

indx

Input: indicates which independent variable is to be deleted from the model.

Constraint: $1 \leq$ **indx** \leq **ip**.

rss

Input: the residual sum of squares for the full regression.

Constraint: $\text{rss} \geq 0.0$.

Output: the residual sum of squares with the (**indx**)th variable removed. Note that the residual sum of squares will only be valid if the regression is of full rank.

fail

The NAG error parameter, see the Essential Introduction to the NAG C Library.

5. Error Indications and Warnings**NE_INT_ARG_LT**

On entry, **ip** must not be less than 1: **ip** = $\langle \text{value} \rangle$.

On entry, **indx** must not be less than 1: **indx** = $\langle \text{value} \rangle$.

NE_2_INT_ARG_LT

On entry **tdq** = $\langle \text{value} \rangle$ while **ip**+1 = $\langle \text{value} \rangle$. These parameters must satisfy $\text{tdq} \geq \text{ip}+1$.

NE_2_INT_ARG_GT

On entry **indx** = $\langle \text{value} \rangle$ while **ip** = $\langle \text{value} \rangle$. These parameters must satisfy $\text{indx} \leq \text{ip}$.

NE_REAL_ARG_LT

On entry, **rss** must not be less than 0.0: **rss** = $\langle \text{value} \rangle$.

NE_DIAG_ELEM_ZERO

On entry, a diagonal element, $\langle \text{value} \rangle$, of R is zero.

NE_ALLOC_FAIL

Memory allocation failed.

6. Further Comments**6.1. Accuracy**

There will inevitably be some loss in accuracy in fitting a model by dropping terms from a more complex model rather than fitting it afresh using nag_regsn_mult_linear (g02dac).

8. Example

A data set consisting of 12 observations on four independent variables and one dependent variable is read in. The full model, including a mean term, is fitted using nag_regsn_mult_linear (g02dac). The value of **indx** is read in and that variable dropped from the regression. The parameter estimates are calculated by nag_regsn_mult_linear_upd_model (g02ddc) and printed. This process is repeated until **indx** is 0.
